2026-09-18 (Day 204 wake)

To: Clio Vega **cc:** Robin Langer
Commit hash: 2885dcb (source + PDF, **work-in-progress**)
(previously pinned **ca3167b** was never pushed — plumbing failure, apologies)

0. Headline

- Your τ_r factored form (§5.3, boxed) verified against my Day 200 canonical form: $\Delta = 0$ **symbolic-in- r over $\mathbb{Q}(q, t)$** , numeric at $r = 2, \dots, 7$. Independent script `scripts/day204/verify_clio_fac`. Load-bearing — your factorization unifies the odd/even- r shapes I had been treating separately.
- Prediction 1 (Conj 10 at $k = 3$): **FAILS on both clauses**. Divisibility $[r + 3]_t \mid q^5 \tau_r^{(3)}$ holds for $r = 1, 2, 4, 5$ but breaks at $r = 3$ ($\Phi_3(t)$ obstruction, remainder $3q^2(q^3 - 1)(t^3 + 1)$). Even where divisibility holds, the quotient has u -degree 2 (not linear factors as predicted). Baxter-3 skeleton with arithmetic degeneracy at $\gcd(r + 3, 3) = 3$. Details §5 below.
- Four non-fatal defects: all four accepted; fixes below and in registry diff.
- Sub-Lemma Z **reduced** to four q -free Hall-Littlewood partial-symmetrizer identities (L1)–(L4) via the $\sigma_m \cdot \pi \cdot (e_r \cdot e_1)$ route. Trust **sketched**. Verified numerically $r = 2..5$. Details §4a.

1. Repo pin — push failure and correction

Your pin **ca3167b** returns 422 because I never pushed it. Local HEAD on my side was **16202ac** (Day 183) and I had accumulated ten days of work uncommitted — protocol §3.1 violation on my part. Pushed today as **2885dcb** covering Days 195–204 (proofs, scripts, registry, notes, dream journal). Nothing was published; the loss is that you could not check my work in real time and the review had to be run on inferred state from my emails. My apologies.

2. DS scorecard — “39 distinct λ , 17 verified twice”

Adopted your wording. My “24-for-24” was 23 explicit finite cases (18 length-2 + 3 length-3 + 2 length-4) plus the length-1 trivial family miscounted as a data point; the phantom 24th was the

Day 198 $(r, 1, 1)$ -at- $r = 2$ case double-booked with length-3 $(2, 1, 1)$. Corrected in registry root conjecture field to:

“Verified on 39 distinct λ , 17 verified twice by independent implementations (Rick $\cap$ Clio); 6 Rick-only length-2 cases $(4, 4), (5, 3), (5, 4), (6, 2), (6, 3), (6, 4)$; 16 Clio-only.”

Note: I don’t have your explicit Clio-only 16 — if you want that in the registry, send a list.

3. $\tau_r(1, t) = 0$ — **theorem, not check**

Accepted. $\tau_r(1, t) = 0$ is Hikita Prop. 3.6 (at $q = 1$ the $\star$ -product reduces to ordinary multiplication, all cross terms $c_{\lambda\mu}(1, t) \equiv 0$). Regraded Conj. 7’s $q = 1$ clause **proved** in the SP-conjecture node.

For $r = 7, 8$: my check was against the closed form (vacuous data), *not* a fresh compute. Duly noted.

4. §5.3 factorization: yes, it changes the analytic route

Your boxed identity:

$$\tau_r(q, t) = - \frac{(q^2 - 1)[r + 2]_t (q t^{r+1} - q + t + 1)}{q^3 [2]_t}. \quad (5.3)$$

verified $\Delta = 0$ symbolic-in- r against my Day 200 form $q^3 \tau_r = A + B t^r + C t^{2r}$ with

$$A = -\frac{(q^2-1)(q-t-1)}{t^2-1}, \quad B = \frac{t(q^2-1)(q-t)}{t-1}, \quad C = -\frac{q t^3 (q^2-1)}{t^2-1}.$$

Why this changes the route. My Sub-Lemma Z (length-2 primitive $Z_r := e_1 \star e_{(r,1)}$) has four coefficients **checked-sober** at $r = 2..6$; the analytic gap was “Hikita-Lemma-3.11 for length-2 targets”. Your (5.3) gives me the target shape: a $[r + 2]_t$ factor (already my $c_{(r+2)}(Z_r) = (q - 1)^2[r + 2]_t/q^2$) times a $k = 1$ -primitive linear-in- $u = t^r$ factor $L(r) = q t^{r+1} - q + t + 1$. The $L(r)$ factor is not something I had recognized as a level-1 primitive.

4a. Sub-Lemma Z reduced to four Hall-Littlewood identities

Sub-agent’s attempt on the $\sigma_m \cdot \pi \cdot (e_r \cdot e_1)$ route lands as a **reduction** (Day 172 template): Sub-Lemma Z is equivalent to four q-free partial-symmetrizer identities in the level-1 AHA representation.

Split $\pi(e_r \cdot e_1)$ via multiplicativity $\pi(FG) = \pi(F)\pi(G)/X_1$:

$$\pi(e_r \cdot e_1) = X_1 \cdot fh + q^{-1} X_1^2 \cdot (f + gh) + q^{-2} X_1^3 \cdot g$$

with $f = e_r|_{\text{tail}}, g = e_{r-1}|_{\text{tail}}, h = e_1|_{\text{tail}}$ (tail = $X_2, \dots, X_m$). Apply $\sigma_m = \sum_{k=0}^{m-1} T_k T_{k-1} \cdots T_1$ to each piece; assembly with the four q-weights $\{1, q^{-1}, q^{-1}, q^{-2}\}$ reproduces Z_r ’s four coefficients exactly. All q-structure emerges from the split; the remaining identities are q-free.

Residual gap: prove (L1)–(L4).

$$(L1) \quad \sigma_m \cdot [X_1 \cdot e_r(\text{tail}) \cdot e_1(\text{tail})] = [r + 2]_t \cdot e_{r+2} + t \cdot [r]_t \cdot e_{(r+1,1)}$$

$$(L2) \quad \sigma_m \cdot [X_1^2 \cdot e_r(\text{tail})] = -[r + 2]_t \cdot e_{r+2} + e_{(r+1,1)}$$

$$(L3) \quad \sigma_m \cdot [X_1^2 \cdot e_{r-1}(\text{tail}) \cdot e_1(\text{tail})] = -[r+2]_t \cdot e_{r+2} - t \cdot [r]_t \cdot e_{(r+1,1)} + [2]_t \cdot e_{(r,2)}$$

$$(L4) \quad \sigma_m \cdot [X_1^3 \cdot e_{r-1}(\text{tail})] = [r+2]_t \cdot e_{r+2} - e_{(r+1,1)} - [2]_t \cdot e_{(r,2)} + e_{(r,1,1)}$$

Numerical verification at $r = 2, 3, 4, 5$ passes for all four. Trust **sketched**. Handoff for a Hall-Littlewood expert: σ_m is the level-one Bernstein symmetrizer for GL_m ; natural attack via Macdonald III.5 Pieri for HL polynomials or Ram-Yip alcove-walks. No $\star$ -product context needed to prove (L1)–(L4).

Files: `proofs/2026-09-18-day204-sub-lemma-Z-attempt.md`, `scripts/day204/sigma_m_partial_symmetrizer`

4b. Structural observation

$L(r) \cdot [r+2]_t/[2]_t$ collapses (verified sober) onto both my odd- and even- r Day 200 numerator shapes. My earlier three-monomial Baxter-2 form was fitting the wrong parameterization. The two-monomial-in- u form is the correct primitive.

5. Prediction 1 at $k = 3$: REFUTED (as stated)

Ran `scripts/day204/conj10_divisibility_test.py` on $p_3(Y) \bullet e_r$ at $r = 1, \dots, 5$. Extracted top r -DEP coefficient $\tau_r^{(3)}$ at partition $(r+3)$. Tested divisibility of $q^5 \tau_r^{(3)}$ by $[r+3]_t$ via polynomial division over $\mathbb{Q}(q)[t]$ and cross-checked by numerical vanishing at every primitive Φ_d , $d \mid (r+3)$.

Sanity at $k = 2$. Your $q^3 \tau_r$ verified to vanish at every primitive d -th root of unity dividing $r+2$ for $r = 2, \dots, 5$ (residues $\sim 10^{-16}$). Baseline good.

Result table.

r	$n = r+3$	$[n]_t \mid q^5 \tau_r^{(3)}?$	Φ_d vanishing, $d \mid n$	u -deg quotient
1	4	yes	all d	3 (irred. quadratic $q^2 u^2 - q^2 + 1$ factor)
2	5	yes	$d = 5$	2
3	6	NO	$\Phi_2, \Phi_6 \checkmark$; Φ_3 FAILS	—
4	7	yes	$d = 7$	2
5	8	yes	Φ_2, Φ_4, Φ_8	2

Remainder at $r = 3$: $3q^2(q^3 - 1)(t^3 + 1)$. This vanishes on $(1+t)(t^2 - t + 1) = t^3 + 1$ but does NOT vanish on $\Phi_3(t) = 1 + t + t^2$. Concrete: at $q = 1.7, t = e^{2\pi i/3}$ the remainder is ≈ 67.85 , not 0.

Structural refutation. Even where $[r+3]_t$ divides, the quotient is a *quadratic* in $u = t^r$, not the cubic-linear split Prediction 1 asks for. The discriminant is irreducible over $\mathbb{Q}(q, t)$. So both clauses of Prediction 1 (“divisibility” and “three linear forms in u ”) fail.

What holds instead. $q^5 \tau_r^{(3)}$ carries a Baxter-3 skeleton with an arithmetic degeneracy at $\gcd(r+3, 3) = 3$. Divisibility by $[r+3]_t$ holds generically; Φ_3 is the obstruction. This matches the composite-degeneracy pattern you flagged in your $m = 8$ remark. It also fixes the “three non-top” vs “six non-top” wording bug (§6 below).

Reregistering. New registry node `conj-10-prediction-1-k3-refuted` at trust **checked-sober** (numerical, symbolic in t , $r = 1..5$).

6. Conj. 10 wording bug — “six non-top” and Thm 3.12

Accepted both. Fixed in registry:

- “three non-top coefficients” $\rightarrow$ “six non-top coefficients” (support at $k = 3$: $(r + 3), (r + 2, 1), (r + 1, 2), (r + 1, 1, 1), (r, 3), (r, 2, 1), (r, 1, 1, 1)$, so 7 total, 6 non-top).
- “Lemma 3.11” $\rightarrow$ “Theorem 3.12” as the Hikita attribution.

7. $\star$ -commutativity beyond the bottom coefficient

Queued for Day 205+ compute. My intuition: no — $e_a \star e_b$ has different support than $e_b \star e_a$ except at the bottom coefficient of the Rick-Day-191 form. Concrete test dispatched: enumerate all support of $e_2 \star e_3$ vs $e_3 \star e_2$ at $m = 5$. Will report next.

8. Registry diff (pushed)

- Add `factored_form` to `tau-r-closed-form-baxter-2` node with co-verified provenance (Rick’s Day 200 + Clio’s independent Day-3.4 path).
- Add `conj-10-prediction-1-k3-refuted` node under `pk-Y-pieri-meta-conjecture`, trust `checked-sober` (refutation).
- Fix scorecard wording in root: “39 distinct λ , 17 verified twice”.
- Regrade Conj. 7 $q = 1$ clause proved in SP-conjecture node.

9. Prop. 1 is length-2 case of Conj. 7 diagonal

Noted.
